### Abstract

This study focuses on how the length of exposure to chilling temperature and atmosphere storage conditions regulate the hydrolytic activity and expression of chitinase (PR-Q) and 1,3- $\beta$ -glucanase (PR-2) isoenzymes in cherimoyas (*Annona cherimola* Mill.). Storage at 6 °C modified the expression of constitutive isoenzymes and induced the appearance of novel acidic chitinases, AChi26 and AChi24, at the onset of the storage period, and of a basic chitinase, BChi33, after prolonged storage. The induction of this basic isoenzyme was concomitant with the accumulation of basic constitutive 1,3- $\beta$ -glucanases. These low-temperature-induced chitinases modified the growth inhibition *in vitro* of *Botrytis cinerea*. Short-term high CO<sub>2</sub> treatment activated a coordinated response of acidic chitinases and 1,3- $\beta$ -glucanases after prolonged storage at chilling temperature. Moreover, the high *in vitro* cryoprotective activity of CO<sub>2</sub>-treated protein extracts was associated with the induction of two low molecular mass isoenzymes, AGlu19 and BChi14. Thus, exposure to high concentrations of CO<sub>2</sub> modified the response of fruit to low temperature, inducing the synthesis of cryoprotectant proteins such as specific pathogenesis-related isoenzymes that could be functionally associated with an increase in chilling tolerance *in vivo*.
